GUI and CLI are not the same, but both have a hand in how computers function. For GUI this is known as Graphical User Interface, and an example would be our modern day Microsoft desktops like windows 11. For windows 11 we are presented with menus all around, from the bottom taskbar to the windows menu this is what makes up the GUI as it is the interactive element of the interface, used via graphics such as sliders, menus, icons, bars, folders etc. to help the user maneuver around their system. For CLI this is Command Line Interface and is very different, as this interface is more text and code related. This being something like MS-DOS which is an operating system that works off of a command shell, this being a window in which the user would type in commands and prompts in order for the system to function and create certain outputs, but now adays CLI isn't as common since the creation of GUI.
